

Create a simple chatbot using **Python or TypeScript/JavaScript**.

The chatbot should:

1. **Answer questions based on static, multi-modal content**
 - Use a small collection of documents in different formats (e.g. **PDF, TXT, Markdown**).
 - Users should be able to ask questions in natural language and receive relevant answers from this content.
2. **Request and return dynamic information**
 - Example: *“How many vacation days do I have left?”*
 - This information should be retrieved **on demand from an external source or service** (this can be mocked or simulated).

Scope & Expectations

- Keep the solution simple; a CLI or minimal UI is sufficient.
- No production-ready system required.
- Focus on **how you structure the solution, separate responsibilities, and integrate external data sources**.
- Clearly document assumptions and design decisions.

After **~3 days**, we'll discuss:

- How you handled different document formats
- How the chatbot decides when to fetch external data
- How the integration with external services works
- What you would change or improve with more time
